XSL / XSLT

- XSL (eXtensible Stylesheet Language) is a styling language for XML.
- XSLT stands for XSL Transformations.
- Used to transform XML documents into other formats (like transforming XML into HTML).

XSL(T) Languages

- **XSLT** is a language for transforming XML documents.
- **XPath** is a language for navigating in XML documents.
- **XQuery** is a language for querying XML documents
- XSL stands for **EX**tensible **S**tylesheet **L**anguage.
- The World Wide Web Consortium (W3C) started to develop XSL because there was a need for an XML-based Stylesheet Language

XSL - More Than a Style Sheet Language

- XSL types
 - XSLT - a language for transforming XML documents
 - XPath - a language for navigating in XML documents
 - XQuery - a language for querying XML documents

XSLT = XSL Transformations

- XSLT is the most important part of XSL.
- XSLT is used to transform an XML document into another XML document, or another type of document that is recognized by a browser, like HTML.
- Normally XSLT does this by transforming each XML element into an HTML element.
- With XSLT, you can add/remove elements and attributes to or from the output file.
- You can also rearrange and sort elements, perform tests and make decisions about which elements to hide and display, and a lot more.
- A common way to describe the transformation process is to say that **XSLT transforms an XML source-tree into an XML result-tree**

Create an XSL Style Sheet

- you create an XSL Style Sheet ("cdcatalog.xsl") with a transformation template

```
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform" version="1.0">
  <script/>
  ▼<xsl:template match="/">
    ▼<html>
      ▼<body>
        <h2>My CD Collection</h2>
        ▼<table border="1">
          ▼<tr bgcolor="#9acd32">
            <th style="text-align:left">Title</th>
            <th style="text-align:left">Artist</th>
          </tr>
          ▼<xsl:for-each select="catalog/cd">
            ▼<tr>
              ▼<td>
                <xsl:value-of select="title"/>
              </td>
              ▼<td>
                <xsl:value-of select="artist"/>
              </td>
            </tr>
          </xsl:for-each>
        </table>
      </body>
    </html>
  </xsl:template>
</xsl:stylesheet>
```

Link the XSL Style Sheet to the XML Document

- Add the XSL style sheet reference to your XML document ("cdcatalog.xml"):

```
<?xml version="1.0" encoding="UTF-8"?>
<?xml-stylesheet type="text/xsl" href="cdcatalog.xsl"?>
<catalog>
  <cd>
    <title>Empire Burlesque</title>
    <artist>Bob Dylan</artist>
    <country>USA</country>
    <company>Columbia</company>
    <price>10.90</price>
    <year>1985</year>
  </cd>
  .
  .
</catalog>
```

XSLT <xsl:template> Element

- An XSL style sheet consists of one or more set of rules that are called templates.
- A template contains rules to apply when a specified node is matched
- The <xsl:template> element is used to build templates.
- The match attribute is used to associate a template with an XML element. The match attribute can also be used to define a template for the entire XML document.
- The value of the match attribute is an XPath expression (i.e. match="/" defines the whole document)

```
<xsl:template match="/">
  <html>
  <body>
    <h2>My CD Collection</h2>
    <table border="1">
      <tr bgcolor="#9acd32">
        <th>Title</th>
        <th>Artist</th>
      </tr>
      <tr>
        <td>.</td>
        <td>.</td>
      </tr>
    </table>
  </body>
</html>
</xsl:template>
```

XSLT <xsl:value-of> Element

- The <xsl:value-of> element can be used to extract the value of an XML element and add it to the output stream of the transformation

```
</tr>
<tr>
  <td><xsl:value-of select="catalog/cd/title"/></td>
  <td><xsl:value-of select="catalog/cd/artist"/></td>
</tr>
</table>
</body>
```

XSLT <xsl:for-each> Element

- The <xsl:for-each> element allows you to do looping in XSLT.

```
</tr>
<xsl:for-each select="catalog/cd">
  <tr>
    <td><xsl:value-of select="title"/></td>
    <td><xsl:value-of select="artist"/></td>
  </tr>
</xsl:for-each>
</table>
```

XSLT <xsl:sort> Element

- To sort the output, simply add an <xsl:sort> element inside the <xsl:for-each> element in the XSL file

```
</tr>
<xsl:for-each select="catalog/cd">
  <xsl:sort select="artist"/>
  <tr>
    <td><xsl:value-of select="title"/></td>
    <td><xsl:value-of select="artist"/></td>
  </tr>
</xsl:for-each>
/table>
```

XSLT <xsl:if> Element

- To put a conditional if test against the content of the XML file, add an <xsl:if> element to the XSL document.

```
<xsl:if test="expression">  
    ...some output if the expression is true...  
</xsl:if>
```

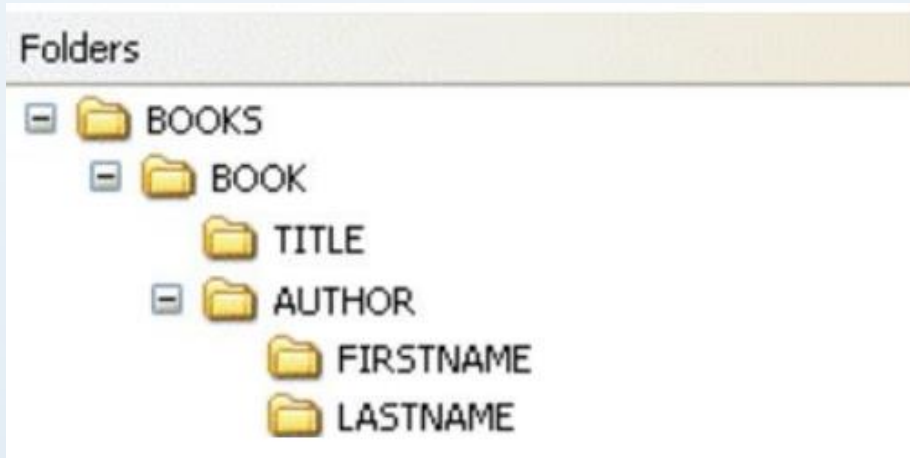

```
<xsl:for-each select="catalog/cd">  
    <xsl:if test="price > 10">  
        <tr>  
            <td><xsl:value-of select="title"/></td>  
            <td><xsl:value-of select="artist"/></td>  
            <td><xsl:value-of select="price"/></td>  
        </tr>  
    </xsl:if>  
</xsl:for-each>
```

XPath

- XPath is a major element in the XSLT standard.
- XPath can be used to navigate through elements and attributes in an XML document.
- XPath stands for XML Path Language
- XPath uses "path like" syntax to identify and navigate nodes in an XML document
- XPath contains over 200 built-in functions
- XPath is a major element in the XSLT standard
- XPath is a W3C recommendation

XPath Path Expressions

- XPath uses path expressions to select nodes or node-sets in an XML document.
- These path expressions look very much like the path expressions you use with traditional computer file systems:

XPath Standard Functions

- XPath includes over 200 built-in functions.
- There are functions for string values, numeric values, booleans, date and time comparison, node manipulation, sequence manipulation, and much more.
- Today XPath expressions can also be used in JavaScript, Java, XML Schema, PHP, Python, C and C++, and lots of other languages

XPath is Used in XSLT

- XPath is a major element in the XSLT standard.
- With XPath knowledge you will be able to take great advantage of your XSLT knowledge

XPath Terminology

- Nodes

- In XPath, there are seven kinds of nodes: element, attribute, text, namespace, processing-instruction, comment, and document nodes.
- XML documents are treated as trees of nodes. The topmost element of the tree is called the root element.
- Example of nodes in the XML document above: ===>

```
<?xml version="1.0" encoding="UTF-8"?>

<bookstore>
  <book>
    <title lang="en">Harry Potter</title>
    <author>J K. Rowling</author>
    <year>2005</year>
    <price>29.99</price>
  </book>
</bookstore>
```

`<bookstore>` (root element node)

`<author>J K. Rowling</author>` (element node)

`lang="en"` (attribute node)

XPath Terminology

- Atomic values
 - Atomic values are nodes with no children or parent.
 - Example of atomic values:

```
J K. Rowling
```

```
"en"
```

Relationship of Nodes

- Parent
 - Each element and attribute has one parent.
 - In the following example; the book element is the parent of the title, author, year, and price:

```
<book>  
  <title>Harry Potter</title>  
  <author>J K. Rowling</author>  
  <year>2005</year>  
  <price>29.99</price>  
</book>
```

Relationship of Nodes

- Children

- Element nodes may have zero, one or more children.
- In the following example; the title, author, year, and price elements are all children of the book element:

```
<book>  
  <title>Harry Potter</title>  
  <author>J K. Rowling</author>  
  <year>2005</year>  
  <price>29.99</price>  
</book>
```

Relationship of Nodes

- Siblings
 - Nodes that have the same parent.
 - In the following example; the title, author, year, and price elements are all siblings:

```
<book>  
  <title>Harry Potter</title>  
  <author>J K. Rowling</author>  
  <year>2005</year>  
  <price>29.99</price>  
</book>
```

Relationship of Nodes

- Ancestors
 - A node's parent, parent's parent, etc.
 - In the following example; the ancestors of the title element are the book element and the bookstore element:

```
<bookstore>

<book>
  <title>Harry Potter</title>
  <author>J K. Rowling</author>
  <year>2005</year>
  <price>29.99</price>
</book>

</bookstore>
```

Relationship of Nodes

- Descendants
 - A node's children, children's children, etc.
 - In the following example; descendants of the bookstore element are the book, title, author, year, and price elements:

```
<bookstore>

<book>
  <title>Harry Potter</title>
  <author>J K. Rowling</author>
  <year>2005</year>
  <price>29.99</price>
</book>

</bookstore>
```

XPath Syntax

- XPath uses path expressions to select nodes or node-sets in an XML document. The node is selected by following a path or steps.

- XML File ==>

```
<?xml version="1.0" encoding="UTF-8"?>

<bookstore>

<book>
  <title lang="en">Harry Potter</title>
  <price>29.99</price>
</book>

<book>
  <title lang="en">Learning XML</title>
  <price>39.95</price>
</book>

</bookstore>
```

Selecting Nodes

- XPath uses path expressions to select nodes in an XML document. The node is selected by following a path or steps.
- The most useful path expressions are listed below:

| Expression | Description |
|-----------------|---|
| <i>nodename</i> | Selects all nodes with the name " <i>nodename</i> " |
| / | Selects from the root node |
| // | Selects nodes in the document from the current node that match the selection no matter where they are |
| . | Selects the current node |
| .. | Selects the parent of the current node |
| @ | Selects attributes |

Selecting Nodes

- In the table below, there are some path expressions and the result of the expressions:

| | |
|-----------------|---|
| bookstore | Selects all nodes with the name "bookstore" |
| /bookstore | Selects the root element bookstore Note: If the path starts with a slash (/) it always represents an absolute path to an element! |
| bookstore/book | Selects all book elements that are children of bookstore |
| //book | Selects all book elements no matter where they are in the document |
| bookstore//book | Selects all book elements that are descendant of the bookstore element, no matter where they are under the bookstore element |
| //@lang | Selects all attributes that are named lang |

XPath Example

- Example from XSLT

```
</tr>
<tr>
  <td><xsl:value-of select="catalog/cd/title"/></td>
  <td><xsl:value-of select="catalog/cd/artist"/></td>
</tr>
</table>
</body>
```

XQuery

- XQuery is to XML what SQL is to databases.
- XQuery is designed to query XML data

```
for $x in doc("books.xml")/bookstore/book
where $x/price>30
order by $x/title
return $x/title
```

XQuery

- XQuery is the language for querying XML data
- XQuery for XML is like SQL for databases
- XQuery is built on XPath expressions
- XQuery is supported by all major databases
- XQuery is a W3C Recommendation
- XQuery can be used to:
 - Extract information to use in a Web Service
 - Generate summary reports
 - Transform XML data to XHTML
 - Search Web documents for relevant information

XQuery Example

- We will use following XML file

```
<bookstore>
  <book category="cooking">
    <title lang="en">Everyday Italian</title><author>Giada De Laurentiis</author>
    <year>2005</year><price>30.00</price>
  </book>
  <book category="children">
    <title lang="en">Harry Potter</title><author>J K. Rowling</author>
    <year>2005</year><price>29.99</price>
  </book>
  <book category="web">
    <title lang="en">XQuery Kick Start</title>
    <author>James McGovern</author>
    <author>Per Bothner</author>
    <author>Kurt Cagle</author>
    <author>James Linn</author>
    <author>Vaidyanathan Nagarajan</author>
    <year>2003</year>
    <price>49.99</price>
  </book>
  <book category="web" cover="paperback">
    <title lang="en">Learning XML</title><author>Erik T. Ray</author>
    <year>2003</year><price>39.95</price>
  </book>
</bookstore>
```

XQuery Example

```
doc("books.xml")/bookstore/book/title
```

- /bookstore selects the bookstore element, /book selects all the book elements under the bookstore element, and /title selects all the title elements under each book element)
- The XQuery above will extract the following:

```
<title lang="en">Everyday Italian</title>  
<title lang="en">Harry Potter</title>  
<title lang="en">XQuery Kick Start</title>  
<title lang="en">Learning XML</title>
```

Predicates

- XQuery uses predicates to limit the extracted data from XML documents.
- The following predicate is used to select all the book elements under the bookstore element that have a price element with a value that is less than 30:

```
doc("books.xml")/bookstore/book[price<30]
```

- The XQuery above will extract the following:

```
<book category="CHILDREN">  
  <title lang="en">Harry Potter</title>  
  <author>J K. Rowling</author>  
  <year>2005</year>  
  <price>29.99</price>  
</book>
```

XQuery FLWOR Expressions

- **For** - selects a sequence of nodes
- **Let** - binds a sequence to a variable
- **Where** - filters the nodes
- **Order by** - sorts the nodes
- **Return** - what to return (gets evaluated once for every node)

XQuery FLWOR Expressions

- Look at the following path expression:

```
doc("books.xml")/bookstore/book[price>30]/title
```

- The expression above will select all the title elements under the book elements that are under the bookstore element that have a price element with a value that is higher than 30
- The following FLWOR expression will select exactly the same as the path expression above:

```
for $x in doc("books.xml")/bookstore/book  
where $x/price>30  
return $x/title
```

```
<title lang="en">XQuery Kick Start</title>  
<title lang="en">Learning XML</title>
```

XQuery FLWOR Expressions

- With FLWOR you can sort the result:

```
for $x in doc("books.xml")/bookstore/book
where $x/price>30
order by $x/title
return $x/title
```

- Result :

```
<title lang="en">Learning XML</title>
<title lang="en">XQuery Kick Start</title>
```
