

CACS-205 Web Technology (BCA, TU)

Ganesh Khatri kh6ganesh@gmail.com

Displaying XML

- Raw XML files can be viewed in all major browsers.
- Don't expect XML files to be displayed as HTML pages.

Most browsers will display an XML document with color-coded elements.

XML HttpRequest

- All modern browsers have a built-in XMLHttpRequest object to request data from a server.
- The XMLHttpRequest object is a developers dream, because you can:
 - Update a web page without reloading the page
 - Request data from a server after the page has loaded
 - Receive data from a server after the page has loaded
 - Send data to a server in the background

Sending an XMLHttpRequest

 A common JavaScript syntax for using the XMLHttpRequest object looks much like this:

```
var xhttp = new XMLHttpRequest();
xhttp.onreadystatechange = function() {
    if (this.readyState == 4 && this.status == 200) {
        // Typical action to be performed when the document is ready:
        document.getElementById("demo").innerHTML = xhttp.responseText;
    }
};
xhttp.open("GET", "filename", true);
xhttp.send();
```

Sending an XMLHttpRequest

The first line in the example above creates an XMLHttpRequest object:

```
var xhttp = new XMLHttpRequest();
```

 The onreadystatechange property specifies a function to be executed every time the status of the XMLHttpRequest object changes:

```
xhttp.onreadystatechange = function()
```

• When readyState property is 4 and the status property is 200, the response is ready:

```
if (this.readyState == 4 && this.status == 200)
```

- The responseText property returns the server response as a text string.
- The text string can be used to update a web page:

XML Parser

- All major browsers have a built-in XML parser to access and manipulate XML.
- The XML DOM (Document Object Model) defines the properties and methods for accessing and editing XML.
- However, before an XML document can be accessed, it must be loaded into an XML DOM object.
- All modern browsers have a built-in XML parser that can convert text into an XML DOM object.

Parsing a Text String

• This example parses a text string into an XML DOM object, and extracts the info from it with JavaScript:

```
<script>
 var parser, xmlDoc firstTitle;
 var text = "<bookstore><book>" +
  "<title>Everyday Italian</title>" +
  "<author>Giada De Laurentiis</author>" +
  "<year>2005</year>" +
  "</book></bookstore>";
 parser = new DOMParser();
 xmlDoc = parser.parseFromString(text, "text/xml");
 firstTitle = xmlDoc.getElementsByTagName("title")[0].childNodes[0].nodeValue;
</script>
```

Parsing a Text String

Example Explained

```
text = "<bookstore><book>" +

"<title>Everyday Italian</title>" +

"<author>Giada De Laurentiis</author>" +

"<year>2005</year>" +

"</book></bookstore>";
```

• A text string is defined: parser = new DOMParser();

The parser creates a new XML DOM object using the text string:

```
xmlDoc = parser.parseFromString(text,"text/xml");
```

The XMLHttpRequest Object

- The XMLHttpRequest Object has a built in XML Parser.
- The responseText property returns the response as a string.
- The responseXML property returns the response as an XML DOM object.
- If you want to use the response as an XML DOM object, you can use the responseXML property.

The XMLHttpRequest Object

```
var xmlhttp = new XMLHttpRequest();
  xmlhttp.onreadystatechange = function() {
    if (this.readyState == 4 && this.status == 200)
      myFunction(this);
  };
  xmlhttp.open("GET", "cd catalog.xml", true);
  xmlhttp.send();
function myFunction(xml) {
  var x, i, xmlDoc, txt; xmlDoc = xml.responseXML;
  txt = "";
  x = xmlDoc.getElementsByTagName("ARTIST");
  for (i = 0; i< x.length; i++) {
    txt += x[i].childNodes[0].nodeValue + "<br>";
  document.getElementById("demo").innerHTML = txt;
```

```
<?xml version="1.0" encoding="UTF-8"?>
<CATALOG>
 <CD>
   <TITLE>Empire Burlesque</TITLE>
   <ARTIST>Bob Dylan</ARTIST>
   <COUNTRY>USA</COUNTRY>
   <COMPANY>Columbia</COMPANY>
   <PRICE>10.90</PRICE>
   <YEAR>1985</YEAR>
 </CD>
 <CD>
   <TITLE>Hide your heart</TITLE>
   <ARTIST>Bonnie Tyler
   <COUNTRY>UK</COUNTRY>
   <COMPANY>CBS Records</COMPANY>
   <PRICE>9.90</PRICE>
   <YEAR>1988</YEAR>
 </CD>
</CATALOG>
```

XML DTD

- DTD stands for Document Type Definition.
- A DTD defines the structure and the legal elements and attributes of an XML document.

Valid XML Documents

- A "Valid" XML document is "Well Formed", as well as it conforms to the rules of a DTD:
- The DOCTYPE declaration above contains a reference to a DTD file.

Note.dtd ======→

```
<!DOCTYPE note
[
<!ELEMENT note (to,from,heading,body)>
<!ELEMENT to (#PCDATA)>
<!ELEMENT from (#PCDATA)>
<!ELEMENT heading (#PCDATA)>
<!ELEMENT body (#PCDATA)>
]>
```

XML DTD

- The DTD above is interpreted like this:
 - !DOCTYPE note Defines that the root element of the document is note
 - !ELEMENT note Defines that the note element must contain the elements: "to, from, heading, body"
 - !ELEMENT to Defines the to element to be of type "#PCDATA"
 - !ELEMENT from Defines the from element to be of type "#PCDATA"
 - !ELEMENT heading Defines the heading element to be of type "#PCDATA"
 - !ELEMENT body Defines the body element to be of type "#PCDATA"
- Tip: #PCDATA means parseable character data.

Using DTD for Entity Declaration

- A DOCTYPE declaration can also be used to define special characters or strings, used in the document:
- Tip: An entity has three parts: it starts with an ampersand (&), then comes the entity name, and it ends with a semicolon (;).

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE note [
<!ENTITY nbsp "&#xA0;">
<!ENTITY writer "Writer: Donald Duck.">
<!ENTITY copyright "Copyright: W3Schools.">
]>
<note>
<to>Tove</to>
<from>Jani
<heading>Reminder</heading>
<body>Don't forget me this weekend!</body>
<footer>&writer;&nbsp;&copyright;</footer>
</note>
```

When to Use a DTD?

- With a DTD, independent groups of people can agree to use a standard DTD for interchanging data.
- With a DTD, you can verify that the data you receive from the outside world is valid.
- You can also use a DTD to verify your own data

When NOT to Use a DTD?

- XML does not require a DTD.
- When you are experimenting with XML, or when you are working with small XML files, creating DTDs may be a waste of time.
- If you develop applications, wait until the specification is stable before you add a DTD. Otherwise, your software might stop working because of validation errors.

XML Schema Definition (XSD)

- An XML Schema describes the structure of an XML document, just like a DTD.
- An XML document with correct syntax is called "Well Formed".
- An XML document validated against an XML Schema is both "Well Formed" and "Valid"
- XML Schema is an XML-based alternative to DTD:

XML Schema: Example

- <xs:element name="note"> defines the element called "note"
- <xs:complexType> the "note" element is a complex type
- <xs:sequence> the complex type is a sequence of elements
- <xs:element name="to" type="xs:string">
 the element "to" is of type string (text)
- <xs:element name="from" type="xs:string"> the element "from" is of type string
- <xs:element name="heading" type="xs:string"> the element "heading" is of type string
- <xs:element name="body" type="xs:string"> the element "body" is of type string

```
<xs:element name="note">
<xs:complexType>
  <xs:sequence>
    <xs:element name="to" type="xs:string"/>
    <xs:element name="from" type="xs:string"/>
    <xs:element name="heading" type="xs:string"/>
    <xs:element name="body" type="xs:string"/>
  </xs:sequence>
</xs:complexType>
</xs:element>
```

XML Schemas are More Powerful than DTD

- XML Schemas are written in XML
- XML Schemas are extensible to additions
- XML Schemas support data types
- XML Schemas support namespaces

- Why Use an XML Schema?
 - With XML Schema, your XML files can carry a description of its own format.
 - With XML Schema, independent groups of people can agree on a standard for interchanging data.
 - With XML Schema, you can verify data

XML Schemas Support Data Types

- One of the greatest strengths of XML Schemas is the support for data types:
 - It is easier to describe document content
 - It is easier to define restrictions on data
 - It is easier to validate the correctness of data
 - It is easier to convert data between different data types

XML Schemas use XML Syntax

- Another great strength about XML Schemas is that they are written in XML:
 - You don't have to learn a new language
 - You can use your XML editor to edit your Schema files
 - You can use your XML parser to parse your Schema files
 - You can manipulate your Schemas with the XML DOM
 - You can transform your Schemas with XSLT

XSD Simple Elements

• A simple element is an XML element that can contain only text. It cannot contain any other elements or attributes.

```
<xs:element name="xxx" type="yyy"/>
```

- where xxx is the name of the element and yyy is the data type of the element.
- XML Schema has a lot of built-in data types. The most common types are:
 - xs:string
 - xs:decimal
 - xs:integer
 - xs:boolean
 - xs:date
 - xs:time

XSD Simple Elements

Here are some XML elements:

```
<lastname>Refsnes</lastname>
<age>36</age>
<dateborn>1970-03-27</dateborn>
```

 And here are the corresponding simple element definitions:

```
<xs:element name="lastname" type="xs:string"/>
<xs:element name="age" type="xs:integer"/>
<xs:element name="dateborn" type="xs:date"/>
```

XSD Complex Elements

- A complex element is an XML element that contains other elements and/or attributes.
- There are four kinds of complex elements:
 - empty elements
 - elements that contain only other elements
 - elements that contain only text
 - elements that contain both other elements and text
- Note: Each of these elements may contain attributes as well!

XSD Complex Elements

- Empty Complex Element
- A complex XML element, "employee", which contains only other elements:

 A complex XML element, "food", which contains only text:

```
cproduct pid="1345"/>
```

```
<employee>
  <firstname>John</firstname>
  <lastname>Smith</lastname>
  </employee>
```

<food type="dessert">Ice cream</food>

```
    A complex XML element,
"description", which
contains both elements and
text:
```

```
<description>
It happened on <date lang="norwegian">03.03.99</date> ....
</description>
```

XSD Attributes

- Simple elements cannot have attributes.
- If an element has attributes, it is considered to be of a complex type.
- But the attribute itself is always declared as a simple type.
- The syntax for defining an attribute is:

```
<xs:attribute name="xxx" type="yyy"/>
```

 where xxx is the name of the attribute and yyy specifies the data type of the attribute.

XSD Attributes

- XML Schema has a lot of built-in data types. The most common types are:
 - xs:string
 - xs:decimal
 - xs:integer
 - xs:boolean
 - xs:date
 - xs:time

```
<lastname lang="EN">Smith</lastname>
```

```
<xs:attribute name="lang" type="xs:string"/>
```

Default and Fixed Values for Attributes

- Attributes may have a default value OR a fixed value specified.
- A default value is automatically assigned to the attribute when no other value is specified.
- In the following example the default value is "EN":

```
<xs:attribute name="lang" type="xs:string" default="EN"/>
```

- A fixed value is also automatically assigned to the attribute, and you cannot specify another value.
- In the following example the fixed value is "EN":

```
<xs:attribute name="lang" type="xs:string" fixed="EN"/>
```

Optional and Required Attributes

 Attributes are optional by default. To specify that the attribute is required, use the "use" attribute:

```
<xs:attribute name="lang" type="xs:string" use="required"/>
```

XSD Restrictions/Facets

- Restrictions are used to define acceptable values for XML elements or attributes.
- Restrictions on XML elements are called facets.

Restrictions on Values

- The following example defines an element called "age" with a restriction.
- The value of age cannot be lower than 0 or greater than 120:

- To limit the content of an XML element to a set of acceptable values, we would use the enumeration constraint.
- The example below defines an element called "car" with a restriction. The only acceptable values are: Audi, Golf, BMW:

- To limit the content of an XML element to define a series of numbers or letters that can be used, we would use the pattern constraint.
- The example below defines an element called "letter" with a restriction. The only acceptable value is ONE of the LOWERCASE letters from a to z:

The next example defines an element called "initials" with a restriction.
 The only acceptable value is THREE of the UPPERCASE letters from a to z:

 The next example also defines an element called "initials" with a restriction. The only acceptable value is THREE of the LOWERCASE OR UPPERCASE letters from a to z:

• The next example defines an element called "choice" with a restriction. The only acceptable value is ONE of the following letters: x, y, OR z:

• The next example defines an element called "prodid" with a restriction. The only acceptable value is FIVE digits in a sequence, and each digit must be in a range from 0 to 9:

Restrictions on Whitespace Characters

- To specify how whitespace characters should be handled, we would use the whiteSpace constraint.
- This example defines an element called "address" with a restriction. The whiteSpace constraint is set to "preserve", which means that the XML processor WILL NOT remove any white space characters:

Restrictions on Length

- To limit the length of a value in an element, we would use the length, maxLength, and minLength constraints.
- This example defines an element called "password" with a restriction. The value must be exactly eight characters:
